1.0 INTRODUCTION

Duke Energy Generation Services (DEGS), formerly Cinergy Solutions of Narrows, LLC operates an industrial power house facility in Narrows, Virginia on the east side of town along the New River. Cinergy Corporation has recently merged with Duke Power. The DEGS power house, formerly owned and operated by Celanese Acetate LLC, operates nine boilers, seven of which are coal-fired boilers, and two of which are natural gas-fired boilers. DEGS boilers exclusively provide process steam and electricity to the Celanese facility.

The Virginia Department of Environmental Quality (VADEQ) has requested that the DEGS Narrows, Virginia facility conduct a BART exemption analysis, since DEGS is a BART-eligible source and possibly subject to regional haze regulations (see February 15, 2006 VADEQ letter). The EPA has issued final guidelines dated July 6, 2005 for the Best Available Retrofit Technology (BART) determinations (70 FR 39104-39172). The regional haze rule includes a requirement for BART for certain large stationary sources. Sources are BART-eligible if they meet three criteria;

1. Potential emissions of at least 250 tons per year of any visibility impairing pollutant
2. Falls within one of the 26 listed source categories in the guidance
3. Was in existence before August 7, 1977 or in operation after August 7, 1962

DEGS Boiler No. 7 is the only unit subject to BART at this time. For any BART-eligible source that can be reasonably expected to cause or contribute to impairment of visibility in any of the 156 federal parks and wilderness (Class I) areas, protected under the regional haze rule, a BART engineering evaluation is required using five factors: 1) existing controls; 2) cost to control; 3) energy requirements and non-air environment impacts of control; 4) remaining useful life of the source; 5) degree of visibility improvement expected from the application of controls. After considering the five factors it is possible that the BART engineering evaluation may result in no controls.

Air quality modeling is an important tool available to the states to determine whether a source can be reasonably expected to contribute to visibility impairment in a Class I area. Class I areas are national parks and wilderness areas in which visibility is more stringently protected under the Clean Air Act than any other areas in the United States. DEGS has retained the services of Trigon Engineering Consultants, Inc. (Trigon) to assist in addressing the impact modeling issues involved with the BART analysis. Trigon

is submitting the following modeling analysis for approval by the VADEQ and the Federal Land Managers (FLM). The FLM and VADEQ reviewed and approved DEGS modeling protocol submitted in May, 2006 with the following conditions (see July 18, 2006 VISTAS protocol revisions):

1. Forego the use of the Ammonia Limiting Method (ALM). DEQ has elected not to apply the ALM for any BART exemption modeling. As a result, a constant background value for ammonia of 0.5 ppb should be used.
2. Use Pasquill-Gifford dispersion coefficients in lieu of turbulence based dispersion coefficients.
3. Calculate natural background conditions using either the "20% best days" method or the annual average method. For this analysis DEQ suggested the use of the annual average method.
4. DEQ recommends the use of the existing IMPROVE algorithm to reconstruct light extinction.

DEGS has adhered to these requests in performing the modeling analysis. The BART exemption modeling was consistent with the guidance in the latest VISTAS protocol (revision 3 – 7/18/06). This document presents the procedures and the results of an air dispersion modeling analysis conducted for the DEGS facility. The modeling was conducted to evaluate whether the DEGS facility may cause or contribute to a visibility impact and therefore be subject to BART. As documented in this report, the modeled visibility impacts from Boiler No. 7 emissions from the DEGS facility are less than 0.5 deciviews (dv). The DEGS, Narrows facility is therefore not subject to BART.

2.0 SOURCE DESCRIPTION AND EVALUATION

2.1 LOCATION OF SOURCES VS. RELEVANT CLASS I AREAS

The DEGS power house is located at 37.34277 North latitude and -80.7675 West longitude (approximate Lambert conformal conic (LCC) coordinates are 1,420.322 kilometers east and -166.335 kilometers north) about 1.9 miles east of Narrows, Virginia along the New River, and approximately 5 miles east of the West Virginia line. DEGS is situated in a deep river valley with significant terrain elevations surrounding the plant and on both sides of the New River (Figure 1). The terrain surrounding the DEGS power house (at 1600 feet MSL) is mountainous, with elevations rising to 3,300 feet (MSL) just 1.5 miles north of the plant. Just to the south across the river, peak elevations exceed 3,600 feet (MSL) 1.8 miles from the plant, and rise to 3,770 feet (MSL) about 2.4 miles south southeast of the plant.

There are seven Class I areas located within 300 km of the DEGS power house site that require evaluation. They are the Dolly Sods and Otter Creek Wilderness Areas in West Virginia, Shenandoa National Park and James River Face Wilderness Area in Virginia, Linville Gorge Wilderness Area, Shining Rock Wilderness Area, Great Smoky Mountains National Park, and Joyce-Kilmer Slickrock Wilderness Area in North Carolina (See Table 1 and Figure 2). All other Class I areas were greater than 300 km away from DEGS. Joyce-Kilmore Slickrock Wilderness was greater than 300 km away, however, since it was within the 50 km buffer zone it was included in the analysis.

2.2 SOURCE IMPACT EVALUATION CRITERIA

DEGS has one BART-eligible unit (PC coal-fired Boiler No. 7) that was evaluated to determine if it is subject to BART requirements. The BART-eligible potential emissions for Boiler No. 7 appear in Table 2. If modeled impacts from the BART-eligible source exceed the threshold value of 0.5 deciviews (dv), then the source is subject to BART. Table 2 summarizes Boiler No. 7 potential-to-emit emission values for SO₂, NO_x, and PM. A source is eligible for BART if potential emissions of visibility-impairing air pollutants are greater than 250 tons per year. Qualifying pollutants include primary particulate matter (PM₁₀) and gaseous precursors to secondary fine particulate matter, such as SO₂ and NO_x. DEGS's Boiler No. 7 has potential emissions of SO₂ and NO_x which exceed the 250 ton per year cutoff, and potential emissions of PM₁₀ which exceed the 15 ton per year *de minimis* level.

2.3 UNIT-SPECIFIC SOURCE DATA

Unit-specific (Boiler No. 7) source data and emission rates for the visibility-impairing pollutants SO₂, NO_x, and PM₁₀ (including speciated data for PM₁₀), appear in Table 3. The emission rates and stack parameters shown in Table 3 were applied in the BART exemption modeling. The daily emission rates utilized in the BART exemption modeling analysis represents potential emission rates for DEGS coal-fired Boiler No. 7. These potential emission rates are based on the boilers design rating of 322 million Btu's per hour and 108,623 tons of coal per year. DEGS used potential emission rates instead of maximum actual emission rates for the highest emitting day over the most recent 3 to 5 year period, since adequate documentation was not available to justify using actual emissions.

Emissions of NO_x, SO₂, SO₄, PM, and secondary organic aerosols were evaluated. PM emissions were speciated into PM₁₀ (PMC or PM Coarse) and PM_{2.5} (PMF or PM Fine). Based upon the latest guidance from VISTAS, DEGS did not evaluate the visibility impacts of volatile organic compounds (VOCs) or ammonia emissions. The stack parameters and emission rates evaluated are provided in Tables 2 and 3. The speciated emission calculations are found in Appendix A.

3.0 BART EXEMPTION MODELING ANALYSIS

3.1 OVERVIEW

According to the BART regulation (FR 39162), a source contributes to visibility impairment in a Class I area if modeled visibility impacts are at least a 0.5 deciview (dv) impact. Sources which do not contribute to visibility impairment in a Class I area are not subject to the BART requirements. This section describes the procedures employed and the results of the modeling conducted in evaluating whether the DEGS facility in Narrows, VA is subject to BART.

The BART exemption modeling analysis involved modeling Boiler No. 7 emissions and comparing modeled impacts to the 0.5 deciview threshold. Since the modeling demonstrates that the BART-eligible emission unit at DEGS contributes less than a 0.5 dv change at any of the eight class I areas, the plant is exempt from further BART review.

The modeling followed EPA's Interagency Workgroup on Air Quality Modeling (IWAQM) and VISTAS guidance. A refined modeling analysis approach, as recommended by the VADEQ, was used in the BART exemption analysis. For the modeling, CALPUFF (version 5.754) was applied with a 3-yr, 4 km sub-regional CALMET meteorological dataset provided by VADEQ. The maximum, 24-hour average value for all receptors in each Class I area was compared to the threshold value of 0.5 dv. It was determined that the maximum value was below the 0.5 dv threshold at all Class I areas. The sub-regional domain 5 covers all of Class I areas shown in Table 1. The 98th percentile value (i.e., the 8th highest value for each year from the full three years) from the 4 km data, as well as the annual average background values, were used in making the comparison to the 0.5 dv criterion.

In creating the CALMET input files, VISTAS used the MM5 databases developed by Earth Tech (TRC) and made available through VISTAS. For the finer resolution sub-domain (4 km grid), available surface and upper air observations were used in addition to MM5 meteorological model outputs.

3.2 MODELING DOMAIN

3.2.1 CALMET Domain

A regional initial domain (12 kilometer grid scale) and a set of pre-computed regional CALMET meteorological files have been prepared by VISTAS, to allow any Class I areas within the VISTAS area to be evaluated with a consistent meteorological database and consistent CALPUFF modeling options. Typically the regional screening modeling results will indicate if a finer resolution run is necessary. However, since the VADEQ has determined that DEGS's only BART-eligible source (Boiler No. 7) has a Q/d (emissions in tons per year divided by distance in kilometers from a Class I area boundary) greater than 10, based on the boilers SO₂ emissions, the VADEQ recommended that DEGS skip the initial first cut screening with the 12 kilometer grid, and instead perform modeling using VISTAS fine grid resolution (4 kilometer grid) for the sub-regional modeling domain number 5. As a result, DEGS conducted the BART exemption modeling with the fine grid resolution in the sub-regional modeling domain. The sub-region domain for CALMET data coverage appears in Figure 3. The CALMET domain location, number of grid cells, and grid spacing are referenced in Table 4.

3.2.2 CALPUFF Domain

Cinergy's boiler No. 7 is located at 37.34277 North latitude and -80.7675 West longitude approximately 2 miles east of Narrows, Virginia. Eight Class I areas are within 300 kilometers of DEGS Boiler No. 7. The CALPUFF computational modeling domain (computational grid) covers all eight Class I areas, including those in Virginia, North Carolina, and West Virginia. The domain covers an area extending 50 kilometers beyond the furthest distance to the affected Class I areas, since the CALPUFF modeling guidance suggests a 50-km buffer zone be included in each direction in establishing the computational modeling domain. The CALPUFF computational domain is smaller than the VISTAS refined CALMET domain 5, and is the area over-which emissions are tracked through puff releases from the Boiler No. 7 stack. The CALPUFF domain is defined by southwest and northeast corners, number of grid cells, and grid spacing, all of which are referenced in Table 4. As shown in Figure 3, the domain extends 561 km in the longitudinal and 510 km in the meridional directions.

3.3 METEOROLOGICAL DATA BASE

3.3.1 MM5 Simulations

The CALMET-ready 4-km MM5 data, produced by Earth Tech and made available through VISTAS, was applied in the fine grid modeling analysis. MM5 meteorological data have been assembled by VISTAS for the BART modeling efforts for the 2001 to 2003 time period.

These datasets have been provided to Earth Tech by VISTAS, and from them Earth Tech has produced annual CALMET meteorological files at 12-km grid resolution for the entire Southeastern Region and at 4-km grid resolution for five sub-regional domains. The CALMET modeling output files in the form of CALPUFF-ready three-dimensional meteorological files have been made available from the States on external hard drives.

3.3.2 Measurements and Observations

Fine grid CALMET simulations were run by Earth Tech in the hybrid mode, using both MM5 data to define the initial guess fields and meteorological observational data. Overwater (buoy) data were provided in addition to the hourly surface meteorological observations, precipitation observations, and twice-daily upper air sounding data.

3.4 CALPUFF INPUT

The VISTAS-provided CALMET output was input to the CALPUFF model, which simulates the effects of the meteorological conditions on the transport and dispersion of pollutants from an individual source. No CALMET runs were therefore required to process meteorological, land use, or terrain data. As a result, CALMET settings are not discussed further.

3.4.1 Emission Data

The pollutant species modeled included SO₂, SO₄, NO_x, and particulate matter in size categories of <0.625 μm, 0.625 to 1.0 μm, 1.0 to 1.25 μm, 1.25 to 2.5 μm, 2.5 to 6.0 μm, and 6 to 10 μm aerodynamic diameters. The particulate matter emissions by size category were combined into the appropriate species for the visibility analysis.

PM₁₀ Specifications:

Elemental Carbon (EC)

Fine PM or “soil” (<2.5 µm in diameter)

Coarse PM (2.5 to 10 µm in diameter)

Organics (secondary organic aerosols (SOA))

Appendix A provides emission calculations for speciated PM₁₀ emissions.

3.4.2 Class I Receptors

DEGS used the FLM Class I receptors for all eight class I areas, with elevations, as obtained from the National Parks Service. The NPS receptors are shown in Figures 2, 4, 5 and 6. The receptor coordinates and elevations are provided in Appendix B.

Receptor locations for the Class I areas are provided by the National Park Service website at <http://www2.nature.nps.gov/air/maps/receptors/index.cfm>. The receptors are created approximately one kilometer apart. Depending on the size of the Class I area, the receptors are then extracted to every second, every third or every fourth receptor in an effort to keep the number of receptors between 100 and 1000 per area. A map of the receptor locations, for each Class I area in North Carolina, Virginia, and West Virginia, appear in Figures 4, 5 and 6.

3.4.3 Control File Settings

In general, DEGS used the default options in the CALPUFF model. Some of the options selected, including deviations from the default values, are discussed below:

- The MESOPUFF II module was used for chemical transformation (MCHEM=1)
- For dispersion, PG dispersion coefficients for rural areas was selected.
- Number of vertical layers (NZ) was set to 10 and cell face heights (ZFACE) of 0, 20, 40, 80, 160, 320, 640, 1200, 2000, 3000, 4000 meters were used (to be consistent with CALMET runs).
- Building downwash was ignored because the Class Areas I are located greater

than 50 km from the source and downwash should not influence concentration estimates.

- Read hourly ozone concentrations from the OZONE.DAT data file.
- Use constant 0.5 ppb values for monthly ammonia concentrations.

3.4.4 Ozone and Ammonia Background Concentrations

CALPUFF uses background ozone (O_3) values in its chemistry module. The model accepts either a single background value or an input file of hourly ozone values commensurate with the period of the meteorological data. DEGS used the observed ozone data for 2001-2003 from CASTNet and AIRS stations. DEGS obtained the O_3 data already extracted from Beeline Software's website. Per VISTAS Guidance, DEGS also used a constant ammonia background value of 0.5 ppb.

3.4.5 Natural Conditions at Class I Areas

The purpose of the CALPUFF modeling is to determine the cause and/or contribution of BART-eligible sources to the impairment of visibility to Class I areas within 300 km of the facility location. The threshold value of delta 0.5 deciviews (δv) is used to determine the affects of the Option C visibility-impairing pollutants SO_2 , NO_x , and PM_{10} , which are emitted from BART-eligible sources. This means that any source resulting in a 0.5 δv change in visibility from the natural conditions at the affected Class I areas may be subject to BART guidelines. The deciview is a unit of measurement of haze, implemented in a haze index (HI) which is derived from calculated light extinction, and which is designed so that uniform changes in haziness correspond approximately to uniform incremental changes in perception across the entire range of conditions, from pristine to highly impaired.

Natural visibility conditions represent the long-term degree of visibility that is estimated to exist in a given mandatory Federal Class I area in the absence of human-caused impairment. These conditions are calculated from the EPA's IMPROVE method using particulate matter to calculate light extinction values. The baseline conditions refer to the conditions on the 20% best visibility days averaged annually. The methods for computing the natural visibility conditions are found in the EPA Guidance for Estimating Natural Visibility Under the Regional Haze Rule. The conditions at each Class I area are shown in Appendix C.

3.5 POSTUTIL AND CALPOST INPUT

3.5.1 Calculation Methods for Background Light Extinction

The CALPOST control file was set such that the background light extinction calculation Visibility Method 6 (MVISBK=6) was used. This is the VISTAS default value as described in the VISTAS protocol document. As required by Method 6, the EPA Class I area-specific monthly relative humidity values f (RH) based on the centroid of each Class I area were used. These values were obtained from Table A-3 of the EPA's "Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule".

In Visibility Method 6, CALPOST also requires monthly background concentrations of ammonium sulfate, ammonium nitrate, coarse particulate mass, organic carbon, soil, and elemental carbon. Annual averages reflective of natural background conditions for these species are available in the EPA's "Guidance for Natural Visibility" document. For each Class I area, this guidance document provides separate deciview values representative of annual average natural background, and natural background for the 20 percent best days.

The EPA natural visibility guidance document however does not provide the speciated background concentrations for ammonium sulfate, ammonium nitrate, coarse particulate, organic carbon, soil or elemental carbon that is representative of the 20 percent best days. As a result, DEGS used a method provided in the revised VISTAS protocol document. Equation 3-2 of the VISTAS protocol document was used to calculate the extinction coefficient that corresponds to the EPA's haze index value for each Class I area. The Rayleigh scattering value of 10 Mm⁻¹ was then subtracted. This value was then entered as the soil concentration (in $\mu\text{g}/\text{m}^3$) in CALPOST. Background values for the other pollutants were set to 0. Appendix C provides the calculation for the background pollutant concentrations for the 20% best days.

3.5.2 Light Extinction Efficiencies and Rayleigh Scattering Value

The other values required to execute CALPOST include the light extinction efficiencies for the pollutant species identified above (i.e., ammonium sulfate, ammonium nitrate, etc.) and the extinction due to Rayleigh scattering (BEXTRAY). Dry extinction efficiencies for the pollutant species were set equal to the Table 2-1 values from the EPA Visibility Guidance Document. The value for Rayleigh scattering was set to 10 Mm⁻¹.

3.6 MODEL RESULTS

The CALPUFF modeling system was executed with input data and settings as described in Sections 2 and 3. Delta-deciview results, necessary for comparison with the 0.5 dv visibility threshold, were obtained from the “24HR VISIBILITY (deciview)” table in the CALPOST output files. CALPOST was run separately for each Class I area in order to obtain the necessary visibility statistics for evaluating compliance with the BART finer grid modeling thresholds. The inputs to CALPOST involve selection of the visibility method (Method 6 in the standard EPA BART guidance), entry of Class I area-specific data for computing background extinction and monthly relative humidity factors for hygroscopic aerosols. The CALPOST output file contains a listing of the highest visibility impact of each day of the model simulation over all receptors included in CALPOST analysis. The peak value of change in extinction is shown at the bottom of the visibility table. The CALPOST processing computes the daily maximum change in deciviews.

In addition to the highest change in deciview value on each day over all the receptors in a particular Class I area, the CALPOST summary table contains the coordinates of the receptor, receptor type (D indicates discrete receptors), the total haze level (background + source, in dv), the background haze in deciviews, the change in haziness (delta dv), the humidity term applied to hygroscopic aerosols ($f(RH)$), and the contribution of each species to light extinction (in percent of the total source contribution) for SO_4 , NO_3 , organics, elemental carbon, coarse and fine particulate matter.

For the fine grid analysis, the data in the CALPOST output was imported into a spreadsheet and sorted on the delta dv column. The ranked visibility impacts (change in dv) were then included in a CALPOST summary table (Table 5) for each of three years and for eight different Class I areas.

The regional haze regulation and BART guideline state that the 98th percentile of 24-hour CALPUFF modeling results are to be compared with the contribution threshold for purposes of determining BART applicability. A 24-hour prediction greater than 0.5 delta-deciview at any receptor in a Class I area would constitute a day of exceedance. Up to 7 days of exceedance are therefore allowed per year per Class I area (i.e., the 98th percentile is approximated by the eighth-highest daily prediction).

The results from the 4 km grid runs are presented in Table 5. As shown, the 98% value is below the 0.5 dv criterion at each Class I area using the annual average values as background. The DEGS Narrows, Virginia facility is therefore exempt from further BART consideration. Model summary output data can

be found in Appendix D. The CALPUFF and CALPOST input and output files are provided on the enclosed CD.

Paper presented at the AAAR International Specialty Conference, PM: Supersite Program and Related Studies, Atlanta, 7-11 February 2005.

**Table 1. Class I Areas Applied In CALPUFF
DEGS, Narrows, Virginia**

Class I ID	Class I Description
otcr	Otter Creek Wilderness
doso	Dolly Sods Wilderness
shen	Shenandoah National Park
jari	James River Face Wilderness
ligo	Linville Gorge Wilderness
shro	Shining Rock Wilderness
grsm	Great Smoky Mountain National Park
joyc	Joyce-Kilmer Slickrock Wilderness

Table 2. BART-ELIGIBLE POTENTIAL EMISSIONS

Pollutant	Boiler No. 7 Emissions (tons/year)	BART Cutoff Level (tons/year)	De Minimis Level (tons/year)	Above Cutoff or De Minimis Levels (Yes/No)
NOx	1,169	250	40	Yes
SO2	1,827	250	40	Yes
PM ₁₀	225	250	15	Yes

Emissions are based on Boiler No. 7 design heat input rating, potential fuel use, and heating value of coal.

Heat Input = 322 mmBtu per hour

Potential Fuel Use = 108,623 tons of coal per year.

Heating Value = 12,984 Btu's per pound of coal.

Table 3. SOURCE SPECIFIC MODELING PARAMETERS

a. Physical Parameters

Source		Location (UTM)			Elevation (m above MSL)	Stack Ht. (m)	Exit Temp. (K)	Exit Vel. (m/sec)	Stack Diam. (m)
Description	Type	X (km)	Y (km)	Zone					
Dry-Bottom PC Boiler # 7 (w/ ESP)	Point	521	4133	17	493	45.72	434	16.76	2.01

Boiler No. 7 is the only BART-eligible source at DEGS.

b. Emission Rates

Pollutant	Emission Rate (lbs/hr)
NO _x	267.01
SO ₂	550.62

Pollutant	Speciation		Emission Rate	
	Description	Name	% (wt)	(lbs/hr)
PM ₁₀	PM Coarse (filterable)	PMC	10.0%	8.45
	PM Fine, Soil (filterable)	PMF	7.7%	6.51
	Elemental Carbon (filterable)	EC	0.3%	0.25
	Inorganic (condensable)	CPM IOR	65.6%	55.27
	Secondary Organic Aerosols (condensable)	CPM OR (SOA)	16.4%	13.82
	TOTALS	---	100.0%	84.30
SO ₄	---	----	----	3.45

Sulfate (SO₄) is assumed to be 5% of total SO₂.

¹ Haze Index (HI) represents the annual average visibility or HI values from Appendix B table of

Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule (2003)

² CALPOST input file, Input Group 2, Additional inputs used for MVISBK = 2, 3, 6, 7

DEGS CALPOST WORKSHEET

Background Light Extinction Calculations for Each Class I Area

Total background light extinction (Mm-1)	bback
Haze index (dv)	HI
Rayleigh scattering coefficient	10
Extinction for all particulates in the background	bray
Extinction for all particulates in the background	bsoil
Extinction coefficient for soil	Csoil
	$bback = 10 * e^{(HI/10)}$
	$bback = bray + bsoil$
	$bback = 10 + bsoil$
	where : HI = annual avg from Appendix B
	bray = 10 Mm-1
	bsoil = bback - bray
Monthly background concentration for soil (BKSOIL)	BKSOIL ($\mu\text{g}/\text{m}^3$) = bsoil/1.0
	where: bsoil = Csoil * BKSOIL
	Csoil = 1.0

Example: $bback = 10 * e^{(3.65/10)}$
HI = 3.65 dv
 $bback = 14.40 \text{ Mm}^{-1}$
 $bback = 10 \text{ Mm}^{-1} + bsoil$
 $bsoil = (14.40 \text{ Mm}^{-1}) - (10 \text{ Mm}^{-1}) = 4.40 \text{ Mm}^{-1}$
 $\text{BKSOIL} = 4.40/1.0 = 4.40 \mu\text{g}/\text{m}^3$

CALPOST Results - 4km CALMET, No ALM (NH_3 @0.5 ppb), Rayleigh at 10 m^{-1} , PG Dispersion Coefficients, Annual Average as Background
